Coin, According to the decouple pre- portion, mentioned by Livy and Julius Pollox, worth

According to the proportion mentioned by Hectus, and which afterwards obtained, whereby the aurer exchanged for _5_ denarii its value

Coin, in architecture, a kind of are cut diagonal, wife, after the manner of a flight of a fluid-cafe, fering in bottom to support columns in a level, and at top to correct the inclination of an entalature fuip- putting a room.

Coin is allo uled for a field angle compofol of two surfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, fcc or interior, as the coin of a chamber or chimary. See Qouo.

COINAGE, or Coining, the art of making ma-ery, as performed either by the hammer or mill.

Remedy the fabric of coins was different from what it is not present. They cut a large piece of metal into federal little figures, the corners of which were cut with shellsers. After having flapped thefele pieces, fo an are reader than perfectly comfortable, point of weight, to the flandard piece, they took each piece in hand again, to make it seemed young people gentle hummering. This was called _Adenez_, and was fit for immediate coming. Then engravers pre-panda, if they fill do, a couple of fleer fits in form of dyes, cut and terminated by flat surface, rounded off at the edges. They engraved or flamped on it the hollow of a head, a cois, a tutendeos, or any other figure, according to to the uniform, the time, with a short legend. As one of thefe dyas was to remain dormant, and the other movable, the former cold in a future prints, this it might be intended into the square hole of the blocks, which, bring fixed very fall, kept the eyes in theory as any vice could have done. The planet of metal has horizontally had upon this inferior mals, to receive the thamp of it on one file, and that of the new dye, wherewith it was covered, on the other. This invisible dye, taking its rough engraved furthest-wing upon the plancher; had at its opposite extremity in flat figures, and larger furties upon which they gave fewer lines show, with a hammer of an enormous fire, till the double thamp was sufficiently, in relleys impressed on each side of the planehet. This being finished, was immediately succeeded by another, and only thus because a functione coin, which had the degree of lineards of the weight and mark, determined by the judgment of the infectors, to make it good current money. The strong tem-pening was wasd is still given to the two dyes, rendering them capable of bearing those expected blows. Coining has been considered, improved and rendered repetitions, by several ingonous machines, and by a wile application of the forell physical expriments to the methods of fixing, drying, and flamping the different results.

The three finest influences the white-man ufes, are the laminating engines: the machine for making the imperfections on the edges of coins, and that null.

After they have taken the laminae, or plates of me-

tal, out of the mould into which they are cafts, they do not best them on the avril, as was formerly done, but they make them pals and repuls between the fe- veral rollers of the laminating engine, which being gradually brought before and defer to the other pro- fently give the lamina its uniform and exact thickensful.

Indeed of dividing the lamina can final figures, they at once even clean out of it as many plantaches as it can contain, by means of a sharp fleet trepan, of a roun- dill figure, hollow within, and of a properizationable diameter, to shape and cut of the pieces at one unit the fames times. After theft glances have been prepared and weighed with witharded pieces, flid or forged to get of the greythours part of the metal, and then boiled and made clear, they arrive, at half, at the mas- chine (fig. r.), which marks them when the edge's and flaming the mail (fig. z). which, squeezing each of them flying between the two dyes, brought near each other with one blow, forces the two furfaces or fields of the piece to fill exactly all the vacations of the two figures engraved hollow. The engine which favors to laminate lead, gives a sufficient notion of that which ferns to flatter gold and fiber: laminae between rollers of a kifefer.

The principal pieces of the machine (fig. x.), to damp coins on the edges, are two fiecl laminae, about a fine thick. One half of the legends, of the ring, is engraved on the thickness of one of the laminain, and the other half on the thickelsof the other; and their two laminar and freightly, although the phanchet marked with them he circular.

When they flump a planches, they fril put it be- borne the flavor in flakes as manas, as that the foils- ing cell of them laid flat upon a scrapeplate, which is faltered upon a every thick wooden table, and the phanche being likewise, laid as the tape of the phanchet may take the time liman or each ride, and in their thick part.

One of the fine lamina isimmorable, and faltered the fewralferesys the other lides by menas of a dented wheel, which takes into the teeth that are on the furties of the laminain. This fitting lamin makes the phanchet runs in flash a mansmy that it remains damaged on the edge, when it has made one turn. Only crown and half-croony pieces can lay the im- prefinion of letters on the thickets of their edges.

The cooling engine or mill is for handy (fig. z.), tuna a fragile man may many twenty thousand plants in one day; golg filters and copper planchets, are all of them cooked with a milk, which the coating liquures (fig. z.), commonly called dyes, are flattened; that of the face under, in a figure box garnified with male and female flowers, to fix and keep it flexily and the other above, in a little box garnished with the fame foresew, to fatten the coming liquare. The plan- chet is laid flat on the liquure of the digty, which is manam; and theý immediately pull the bar of the mill by its cords, which can confer the frewef fet within it to turn. This enters into the female fever, which is in the body of the mill and turns with in each through, that by pushing the upper liquare upon that of the effigor, the plainly violently prefilled between both figures, receives the important of both at one pull, and in the twinkling of an eye.

COIN, in architecture, a kind of dye cut diagonalwife, after the manner of a flight of a ſtair-caſe, ſerving at bottom to ſupport columns in a level, and at top to correct the inclination of an entablature ſupporting a vault.

COIN is alſo uſed for a ſolid angle compoſed of two ſurfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, &c. or interior, as the coin of a chamber or chimney. See QUOIN.

COINAGE, or COINING, the art of making money, as performed either by the hammer or mill.

Formerly the fabric of coins was different from what it is at preſent. They cut a large plate of metal into ſeveral little ſquares, the corners of which were cut off with ſheers. After having ſhaped theſe pieces, ſo as to render them perfectly conformable, in point of weight, to the ſtandard piece, they took each piece in hand again, to make it exactly round by a gentle hammering. This was called a *planchet*, and was fit for immediate coining. Then engravers prepared, as they ſtill do, a couple of ſteel maſſes in form of dyes, cut and terminated by a flat ſurface, rounded off at the edges. They engraved or ſtamped on it the hollow of a head, a croſs, a ſcutcheon, or any other figure, according to the cuſtom of the times, with a ſhort legend. As one of theſe dyes was to remain dormant, and the other moveable, the former ended in a ſquare priſm, that it might be introduced into the ſquare hole of the block, which, being fixed very faſt, kept the dye as ſteady as any vice could have done. The planchet of metal was horizontally laid upon this inferior maſs, to receive the ſtamp of it on one ſide, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved ſurface reſting upon the planchet, had at its oppoſite extremity a flat ſquare, and larger ſurface, upon which they gave ſeveral heavy blows, with a hammer of an enormous ſize, till the double ſtamp was ſufficiently, in relievo, impreſſed on each ſide of the planchet. This being finiſhed, was immediately ſucceeded by another, and they thus became a ſtandard coin, which had the degree of fineneſs of the weight and mark determined by the judgment of the inſpectors, to make it good current money. The ſtrong tempering which was and is ſtill given to the two dyes, rendering them capable of bearing thoſe repeated blows. Coining has been conſiderably improved and rendered expeditious, by ſeveral ingenious machines, and by a wiſe application of the fureſt phyſical experiments to the methods of fining, dyeing, and ſtamping the different metals.

The three fineſt inſtruments the mint-man uſes, are the laminating engine; the machine for making the impreſſions on the edges of coins; and the mill.

After they have taken the laminæ, or plates of metal, out of the mould into which they are caſt, they do not beat them on the anvil, as was formerly done, but they make them paſs and repaſs between the ſeveral rollers of the laminating engine, which being gradually brought cloſer and cloſer to each other, preſently give the lamina its uniform and exact thickneſs. Inſtead of dividing the lamina into ſmall ſquares, they at once cut clean out of it as many planchets as it can contain, by means of a ſharp ſteel trepan, of a roundiſh figure, hollow within, and of a proportionable diameter, to ſhape and cut off the piece at one and the ſame time. After theſe planchets have been prepared and weighed with ſtandard pieces, filed or ſcraped to get off the ſuperfluous part of the metal, and then boiled and made clean, they arrive, at laſt, at the machine (fig. 1.), which marks them upon the edge; and finally, the mill (fig. 2), which, ſqueezing each of them ſingly between the two dyes, brought near each other with one blow, forces the two ſurfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which ſerves to laminate lead, gives a ſufficient notion of that which ſerves to flaten gold and ſilver laminæ between rollers of a leſſer ſize. Coinage. Plate CXLIV.

The principal pieces of the machine (fig. 1.), to ſtamp coins on the edge, are two ſteel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thickneſs of one of the laminæ, and the other half on the thickneſs of the other; and theſe two laminæ are ſtraight, although the planchet marked with them be circular.

When they ſtamp a planchet, they firſt put it between the laminæ in ſuch a manner, as that theſe being each of them laid flat upon a copper-plate, which is faſtened upon a very thick wooden table, and the planchet being likewiſe laid flat upon the ſame plate, the edge of the planchet may touch the two laminæ on each ſide, and in their thick part.

One of theſe laminæ is immoveable, and faſtened with ſeveral ſcrews; the other ſlides by means of a dented wheel, which takes into the teeth that are on the ſurface of the lamina. This ſliding lamina makes the planchet turn in ſuch a manner, that it remains ſtamped on the edge, when it has made one turn. Only crown and half-crown pieces can bear the impreſſion of letters on the thickneſs of their edges.

The coining engine or mill is ſo handy (fig. 2.), that a ſingle man may ſtamp twenty thouſand planchets in one day: gold, ſilver, and copper planchets, are all of them coined with a mill, to which the coining ſquares (fig. 3.), commonly called dyes, are faſtened; that of the face under, in a ſquare box garniſhed with male and female ſcrews, to fix and keep it ſteady; and the other above, in a little box garniſhed with the ſame ſcrews, to faſten the coining ſquare. The planchet is laid flat on the ſquare of the effigy, which is dormant; and they immediately pull the bar of the mill by its cords, which cauſes the ſcrew ſet within it to turn. This enters into the female ſcrew, which is in the body of the mill, and turns with ſo much ſtrength, that by puſhing the upper ſquare upon that of the effigy, the planchet, violently preſſed between both ſquares, receives the impreſſion of both at one pull, and in the twinkling of an eye.
