Vegetable time, and repasted proofs of the good quality of the fluid. At the end of eight more difficult I drew

250. "The fire muff be taken from beneath the re- tort as soon as the definition a fabulist, not only to prevent the effect of the gefone vapour, which fill continue flowly to escape, from selling on the sides of the tub, but likewise disfigned the restore or bodies receive a quantity of warm water, which is to be pound in up or the neck. There is no need to form an excess of quantity and the hotter the veffles are an better. It is effential, however, that it be not poured in cold, for fear of breaking while. The adapter is then to be knitted from the neck of the under tube, If it is repeated photoss and in order that to vapour may escape into the workshop, a kick of hate or a cook may be applied to the bank of the adopter. The find hand easily permits the resort to our ruled and returned again to its place as well as the application of the lins or Dopper to the neck of the adopter, this lift being ruled with one hand while the coat is put in with the other.

"Nevertheless, as the lists which connect the adopter with the rester of downward different towards the end of the operation, it would be more proident to leave every thing in its place, for fear of damaging thief hates. This danger is greater when the adopters is of lead, because the great length of this additional piece tends to force the hitting full now on the account. If it be required to proceed immediately to a new dif utilities, the reason or basis with a capable e pan mult be immediately taken from the furnace, and un- the fluidbulated in its place ready prepared during the former distillation. This specifically requires a double fet of veffels.

211. When the chilling veffil I told, a nearly fo, the whole of its content muff be shaken, by haluding this veffel by the neck with one hand, and apply ing the other to its bottom. The Dopper muff then be taken out, and the veffel greatly affected, taking the refuders to facilitate to charge. In the left man- tion the event it to be held by the neck with one hand, and its fate gently setting against the other. The veff fits into which the water and refundal matter of the restors the poured, found rather for of however, po- ttery, or both than if wood, that feels left bit of veffle fish, which can feel fullyed to dry in the past above the fluid. If this circumstance be not attended to, there will be danger of doing great years due to contents.

"It is much convenient to disregage the rettors or bodies that they are full warm, which continues to be the odds the next morning after distillation, in con- ference of the heat of the fluid bath. If they be left to cool entirely, the filphate of folda will crystallize, and it will be necessary to dilutive in hot water fish

larger portions as cannot pas through the neck. But Vegetable this inconvenience is not likely to happen, united the ^{thickness}.

of one-fourth of the contents of the veffly a bound fourth two hours afterwards; a third fourth after ten hours and a half of eleven hours; and the reffi after twelve hours affiliation, who formed the conditions.

quality matter had added by too final, just the six dides have been left undilluted for several days. The fame operation is applicable to that kind of breath- tion which is formed by the monitor, it not properly pulseier), dried, or mixes; this cannot be separated from the bottom of the extent, like by means of lost water poured at different facective times. It is like- wite details to leave on craft or depletion of murals, no other

matter, in the veffle which are recorded, un- left the fans be moveable, in which cafe the rifk is left. But if the average of building should then re- viser that the fans veffle be uful without entirely clearing them, it will be exceedingly to range this excl- end matter on one side, where it will be led exposed to the heat, and will afford a greater degree of facility for the nitric acid and it upon in.

When the liquor is entirely worn off from the veffel, it must not be immediately filled with water, or at least to the height of five or its inches above the return of the leader tube, otherwise the gas, which continues to escape from the difficulty veffle then affords no refinance, might attack the pneumatic veffel inficit.

In order that the vapour which exales from the diltilling veffils may not prove inconvenient, it is seccillary to poor in a small quantity of alkaline trivium in the first place, which ultimately defroys the finals. This may be done immediately after the end of the difficulties, and the weak alkaline nutrition therapy the place of the water used for diluting the refuders. But the failure of pouring this little water s, along effecrécence takes place (for which reduce it in po- per to your it in by several facective portions, waiting still have some cash time.

252. The oxygenated lawprepare in this way is Dr. Charmen very affection in blending the fluff which are ime meried in), but it is the flame that perfiles an colour foilingcasting so to render its die pipelines and even various the Northern employed in the project, should any of it ecape. "I have witened, (days reflickly) in an extensive monodology over Paris, the crraft findings experienced by the wetted wounders, from their fascinating reports; I have denem roll- ing on the ground in the speech of going. Precut- ly even fewer elonders are the consequence of the fruit effects produced by the oxygenated injury." She p.Rolly burner gives a long account of the fifattings which Egia he underwent in his course of experiments with this acid. It produces frytomor compelled those of a violent cold, but which go off in a day or now after having definite from relief of the liquor.

This inconvenience was be avoided in two ways;

37. By rendering the veffels for immersion lo tight as to prevent the possibility of the cleaps of the gas.

49. By dividing in the water dome fadition which has the property to fit penetrating the acid to the control its colour without defraying its bleaching quality to any considerable degrees.

57. Mr Marup of Manchester contributed a tu for attention, which ultimately adapted to niver the frift purple. Its contribution is simple, and not ex- petience.

"It would, therefore, be desirable to have an apparatus for the de la the pure oxygenated muratric acid imply different in water, which is at some chopped and bell vehicle for it. This apparatus must the limp in its condition, and distribute an automatic exposure; it muff confine the liquor in such a manner as to prevent the cleaps of the oxygenated muratric acid gas, which is not only a loft of power, but alo an inconvenmence

Vegetable Substances.

time, and repeated proofs of the good quality of the fluid. At the end of eight hours diſtillation, I drew off one-fourth of the contents of the veſſel; a ſecond fourth two hours afterwards; a third fourth after ten hours and a half, or eleven hours; and the reſt after twelve hours diſtillation, which formed the concluſion.

"When the liquor is entirely drawn off from the veſſel, it muſt again be immediately filled with water, or at leaſt to the height of five or ſix inches above the return of the leaden tube, otherwiſe the gas, which continues to eſcape from the diſtilling veſſel and then affords no reſiſtance, might attack the pneumatic veſſel itſelf.

250. "The fire muſt be taken from beneath the retort as ſoon as the diſtillation is finiſhed, not only to prevent the effect of the gaſeous vapours, which ſtill continue ſlowly to eſcape, from acting on the ſides of the tub, but likewiſe to diſpoſe the retorts or bodies to receive a quantity of warm water, which is to be poured in up to the neck. There is no reaſon to fear an exceſs of quantity, and the hotter the veſſels are the better. It is eſſential, however, that it be not poured in cold, for fear of breaking the glaſs. The adopter is then to be unluted from the neck of the leaden tube, if the operator chooſes; and in order that no vapour may eſcape into the workſhop, a bit of lute or a cork may be applied to the beak of the adopter. The ſand bath eaſily permits the retort to be raiſed and returned again to its place, as well as the application of the lute or ſtopper to the neck of the adopter, this laſt being raiſed with one hand while the cork is put in with the other.

"Nevertheleſs, as the lutes which connect the adopter with the retort are ſomewhat ſoftened towards the end of the operation, it would be more prudent to leave every thing in its place, for fear of deranging thoſe lutes. This danger is greater when the adopter is of lead, becauſe the great length of this additional piece tends to force the luting ſtill more on that account. If it be required to proceed immediately to a new diſtillation, the retort or bottle with its capſule or pan muſt be immediately taken from the furnace, and another ſubſtituted in its place ready prepared during the former diſtillation. This neceſſarily requires a double ſet of veſſels.

251. "When the diſtilling veſſel is cold, or nearly ſo, the whole of its contents muſt be ſhaken, by holding this veſſel by the neck with one hand, and applying the other to its bottom. The ſtopper muſt then be taken out, and the veſſel ſpeedily inverted, ſhaking the reſidue to facilitate its eſcape. In this laſt ſituation the retort is to be held by its neck with one hand, and its ſide gently reſting againſt the other. The veſſels into which the water and reſidual matter of the retorts are poured, ſhould rather be of ſtoneware, pottery, or lead, than of wood, unleſs theſe laſt be oil veſſels, which are leſs ſubject to dry in the part above the fluid. If this circumſtance be not attended to, there will be danger of loſing great part of the contents.

"It is moſt convenient to diſengage the retorts or bodies while they are ſtill warm, which continues to be the caſe the next morning after diſtillation, in conſequence of the heat of the ſand bath. If they be left to cool entirely, the ſulphate of ſoda will cryſtallize, and it will be neceſſary to diſſolve in hot water ſuch larger portions as cannot paſs through the neck. But this inconvenience is not likely to happen, unleſs the quantity of water laſt added be too ſmall, and the reſidues have been left undiſturbed for ſeveral days. The ſame obſervation is applicable to that kind of incruſtation which is formed by the muriat, if not properly pulveriſed, dried, or mixed; this cannot be ſeparated from the bottom of the retort, but by means of hot water poured at different ſucceſſive times. It is likewiſe eſſential to leave no cruſt or depoſition of muriat, or other matter, in the veſſels which are emptied, unleſs the ſame be moveable, in which caſe the riſk is leſs. But if the urgency of buſineſs ſhould then require that the ſame veſſels be uſed without entirely clearing them, it will be neceſſary to range this reſidual matter on one ſide, where it will be leſs expoſed to the heat, and will afford a greater degree of facility for the nitric acid to act upon it.

Vegetable Subſtances.

"In order that the vapour which exhales from the diſtilling veſſels may not prove inconvenient, it is neceſſary to pour in a ſmall quantity of alkaline lixivium in the firſt place, which inſtantly deſtroys the ſmell. This may be done immediately after the end of the diſtillation, and the weak alkaline ſolution may ſupply the place of the water uſed for diluting the reſidues. At the inſtant of pouring this lixivial water, a ſtrong effervescence takes place; for which reaſon it is proper to pour it in by ſeveral ſucceſſive portions, waiting a little between each time *."

* *Nicholſ. De Charmes.*

252. The oxygenated liquor prepared in this way is very effectual in bleaching the ſtuffs which are immerſed in it, but it at the ſame time poſſeſſes an odour ſo ſuffocating as to render its uſe unpleaſant and even injurious to the workmen employed in the proceſs, ſhould any of it eſcape. "I have witneſſed, (ſays O'Reilly) in an extenſive manufactory near Paris, the cruel ſufferings experienced by the wretched workmen, from theſe ſuffocating vapours; I have ſeen them rolling on the ground in the exceſs of agony. Frequently even ſevere diſorders are the conſequence of the firſt effects produced by the oxygenated liquor†." De Charmes gives a long account of the ſufferings which he underwent in his courſe of experiments with this acid. It produces ſymptoms completely reſembling thoſe of a violent cold, but which go off in a day or two after having deſiſted from the uſe of the liquor.

† *O'Reilly Eſſai.*

This inconvenience may be avoided in two ways;

1*ſt*, By rendering the veſſels for immerſion ſo tight as to prevent the poſſibility of the eſcape of the gas,

2*dly*, By diſſolving in the water ſome ſubſtance which has the property of ſo far neutralizing the acid as to connect its odour without deſtroying its bleaching quality to any conſiderable degree.

253. Mr Rupp of Mancheſter contrived a tub for immerſion, which is admirably adapted to anſwer the firſt purpoſe. Its conſtruction is ſimple, and not expenſive.

"It would, therefore, be deſirable to have an apparatus for the uſe of the pure oxygenated muriatic acid ſimply diſſolved in water, which is at once the cheapeſt and beſt vehicle for it. This apparatus muſt be ſimple in its conſtruction, and obtainable at a moderate expence; it muſt confine the liquor in ſuch a manner as to prevent the eſcape of the oxygenated muriatic acid gas, which is not only a loſs of power, but alſo an inconvenience
